

# RIPENCC, Oregon Route Views & AMSIX

Comparative analysis of BGP update metrics

Alexander Tudor, Agilent Labs

RIPE 46, Amsterdam, September 1, 2003

**Agilent Technologies**

# Agenda

- **Rationale**
- **Metric Taxonomy**
- **Methodology**
- **Results**
- **Conclusions**
- **Credits**

# Rationale

- Rationale
- Metric Taxonomy
- Methodology
- Results
- Conclusions
- Credits

- Degree of similarity amongst collection points
- Effects of single/multi hop & keep alive on/off
- Geographic correlation

# Metric Taxonomy

- Rationale
- Metric Taxonomy
- Methodology
- Results
- Conclusions
- Credits

- # announcements
- # withdrawals
- # AS path changes (per peer prefix sum)

# Methodology I

- Rationale
- Metric Taxonomy
- Methodology
- Results
- Conclusions
- Credits

## •Collection points:

- RIPENCC – multi hop, keep alive off
- Oregon Route Views – multi hop, keep alive on
- AMSIX – single hop, keep alive on

## •Select time period with following characteristics:

- continuous collection at all three points
- small # of erroneous update packets ( illegal attributes, type 14 usually )
- contains traffic originating in all three geographies
- daily prefix activity

## •Extract metrics data vectors ( one measurement point every 15 minutes )

## •Compute time cross-correlation & compare metric distributions

# Methodology II

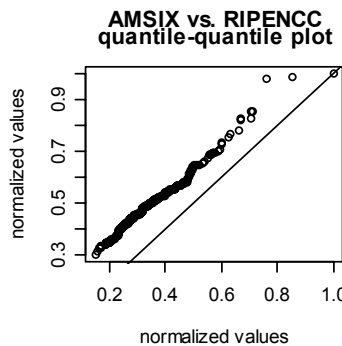

- Rationale
- Metric Taxonomy
- Methodology
- Results
- Conclusions
- Credits

- Study period is April 3 through 5, 2003
- All peers included at each location
- < %0.1 updates lost due to illegal update attribute packets
- 132 prefixes were active daily ( 9 beacons )
- 7x/16, 2x/18, 4x/19, 3x/20, 4x/21, 5x/22, 7x/23, 100x/24
- 60x ARIN, 29x APNIC, 31x RIPE, 12x LACNIC

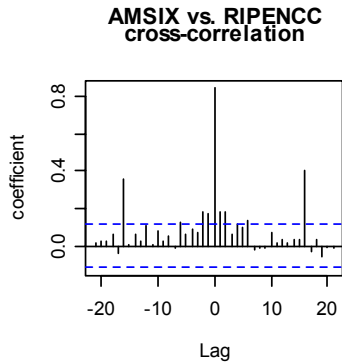

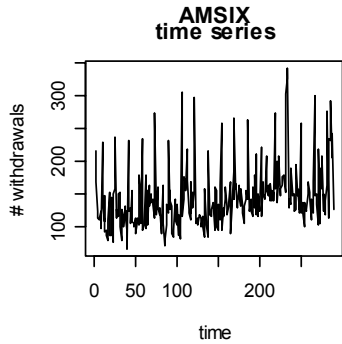

# Results - Announcements

- Rationale
- Metric Taxonomy
- Methodology

- Credits

# Conclusions – I

- Rationale
- Metric Taxonomy
- Methodology
- Results
- Conclusions
- Credits

- There is strong cross-correlation between the time series of all metrics at all three collection points**
- The strongest cross-correlation occurs at zero lag ( good metric synchronization within 15 minutes )**
- Some metrics have better distribution similarity ( withdrawals and AS path changes vs. announcements )**
- Metrics are well synchronized independent of single/multi hop, keep alive on/off & geography**
- Multi/single hop metric distributions similarities are weaker**

# Conclusions – II

- Rationale
- Metric Taxonomy
- Methodology
- Results
- Conclusions
- Credits

## •Announcements:

- are better time correlated between multi-hop collectors ( 0.9 vs. 0.6 )
- AMSIX has higher median values than either RIPENCC or Oregon
- quantile-quantile plot shows high degree of similarity between multi-hop locations;weaker similarity between single/multi hop

## •Withdrawals:

- time correlate well ( 0.9 ) in all cases
- quantile-quantile plot shows strong distribution similarity between multi-hop locations; weaker similarity between single/multi hop

## •AS path changes:

- time correlate well ( 0.9 ) in all cases
- quantile-quantile plot shows strong distribution similarity in all cases

# Conclusions III – So What ?

- Rationale
- Metric Taxonomy
- Methodology
- Results
- Conclusions
- Credits

- Prefix metrics at all locations are interchangeable**
- Metrics are independent of geography in 15 minute buckets**
- Metrics are not sensitive to number of peers or their type ( full-feed or partial )**

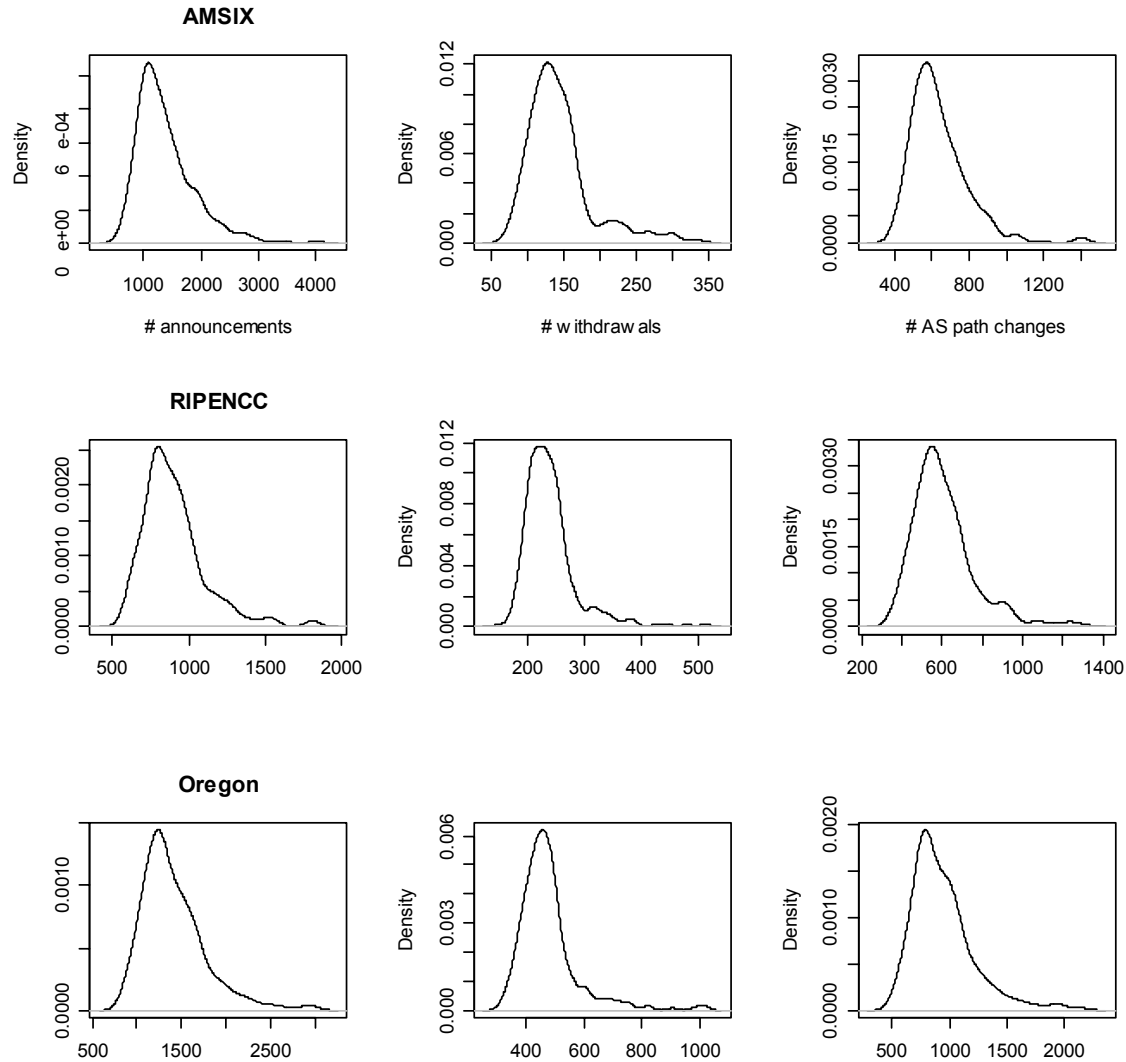

# Credits

- **RIPENCC RIS team**
- **Oregon Route Views team**
- **Jonathan Li, Agilent Labs**

# Results – Distribution Densities

# Results – Community changes
